> In addition to these maps, another map, by Witkind which discusses the seismicity of the Big Fork-Avon area, has been published as U.S. Geological Survey Miscellaneous Field Studies Map MF-923 and is titled Major active faults and seismicity in and near the Big Fork-Avon area, northwestern Hontana.

Surficial deposits

Most of the surficial deposits in the southern part of the file Fork-Avon area were formed primarily during neveral advances and subsequent melts of large glaciers. The first advance recognized locally probably occurred about 150,000 years ago, during the Bull Lake Glaciation of the Pleistocene, when ice from the mountains to the north spread southward across the Blackfoot River. Deposits of this glacier are shows on the maps by the letters "bl" added to the symbol, thus "Ochi--Till deposited by Sull Lake(?) ice." Subsequently, some 78,800 to 30,000 years ago during the Pinedale Glaciation of the Fleistocene, another glacier again moved southward loto the area. It apparently reached almost as far south as Helmville, before it withdrew and then readvanced again. This readvance, however, did not extend as far to the south, probably reaching only to Kleinschmidt Lake. Deposits of these two advances have also been differentiated on the map. The deposits of the first, or older, advance are shown on the map by the letter "o" added to the symbol, thus "Qto-Till deposited by older ice." The deposits of the second, or younger advance, are shown on the map by the letter "y" added to the symbol, thus, "Gty-Till deposited by younger

In addition to the debris, mainly till, deposited by the ice, other naterial, chiefly sand and gravel, was carried far to the south by the meltwaters of the wasting glaciers. These deposits, torsed outwash, are similarly identified on the man by the letters "bl" or "o" or "g" depending upon which glacier furnished them.

In some localities deposits of more than one ice advance may have been inedvertently grouped and thus mapped as the deposits of a single

The eleven maps in the set (79-437 through 79-447) are part of a series prepared as a result of a cooperative venture between Missoula and Powell Counties, Montana and the U.S. Geological Survey. Weber, the

senior author, at one time served as geologic consultant to the counties, and he is primarily responsible for the geologic mapping of the southern half of the Big Fork-Avon area. Witkind mapped the porthern half of the area and his maps are available as Open-File Reports (listed below). Weber is now a geologist with the U.S. Forest Service in Great Falls, Montana; Witkind is a geologist with the U.S. Geological Survey in Benver, Colorado.

The area studied extends from the Big Fork Quadrangle on the north to the Avon Quadrangle on the south (see index map). All the maps are products of that study and are intended for use by sovironmental and land-use planners.

Copies of the available maps can be purchased from:

Open File Services Section, Branch of Distribution, Box 25025, Federal Center, Deover, Colorado 80225

The maps can also be examined at the following offices:

Denver Public Inquiries Office. U.S. Geological Survey, 1017, Federal Suilding, 1961 Stout Street, Denver, Colorado 80202 Salt Lake City Public Inquiries Office,

U.S. Geological Survey. 8015, Federal Office Building, 125 South State Street Salt Lake City, What 84111

DESCRIPTION OF MAP UNITS

This is a combined map description for quadrangles in the southern part of the Big Fork-Awon environmental study area (Open-File Reports 79- 437 to 79-447). Not all units will appear on all maps.l.

- ALLOVIUM (MOLOCENE) -- Light to dark gray and brownish gray: stream-deposited, unconsolidated, moderately to wellbedded, interstratified assemblage of silt, sand, and gravel. Typically clay-rich and cohesive where incised into claystones, siltstones, and shales of older basinfill deposits. Cold-bearing sand and gravel occur locally in the northward-draining valleys of the Carnet Range, and in the westward-draining valleys of the mountains east of Relaville and Avon. Characterized by shallow depths to ground water. Soil drainage is poor and shrink-swell potentials are inferred to be relatively low
- ALLUVIAL FAN DEFOSITS (HOLOGENE) -- Small, moderately sloping, poorly sorted, crudely stratified silt, sand, gravel, cobbles, and boulders at the mouths of small gullies and high-gradient streams. Ground-water conditions are quite variable, and flash-flood hazard potential is high, expecially near the upper apex of the fan. Shrink-swell potential is inferred to be generally low
- COLLEVIUM (HOLOCENE) -- Unsorted debris that has slid or been washed downslope to fore small, thin, and hummocky deposits. Best developed in terrane underlain by Tertiary volcanic rocks. Shrink-swell potentials are variable, and are inferred to range from moderate to high
- LANDSLIDE DEPOSITS (QUATERNARY) -- Small, fan- and lobate-shaped hummocky masses of semiconsolidated soil, till, Tertiary basin fill, and volcanic debris. Clay and soil-moisture content are generally high. Small springs or seeps are common. Many of these landslides are active and all should be considered unstable. Shrink-swell potentials are variable, and are interred to range from moderate to
 - SEDIMENTS DEPOSITED BY MELTWATERS OF PIREDALE GLACIATION (QUATERNARY) -- YOUNGER ICE
- Lacustrine Deposits -- Pink; rhythmically bedded wilt, sandy silt, and clay with included lenses of sand and gravel. Forms gently sloping, smooth surfaces at altitudes generally below 1,158 m (3,800 ft). Soil frainage ranges from fair to poor, but lateral permeability may be high within the interbedded sandy beds and lenses. Bign frostheave susceptibility. Clay-rich beds have a moderate shrink-swell potential
 - Ice-Contact Deposit -- Dark brown and brown; composed of moderately well sorted silt, sand, and gravel. Forms an elongate, gently sloping bench. Clasts range to shape from angular to rounded; most are rounded. Sizes range from 3 mm to 20 cm (1/8-8 in.); dominant sizes range from 13 mm to 5 cm (1/2-2 in.). Dobbles and small engular to rounded boulders 0.6-1 a (2-3 ft) are scattered across the surface. Formed in contact with wasting ice
 - Kame Deposits -- Dark brown and brown; constats of understaly to poorly sorted sitt, sand, and gravel. Forms small, conical to ellipsoidal, steep-sided hillorks. Few wellrounded cobbles scattered irregularly through the omit. Formed by a glacial stream that flowed down into a
 - Outwash -- Light brown, and grayfah brown; moderately well sorted; composed of silt, sand, and subrounded to rounded pebbly and cobbly gravel. Commonly the upper 1 m (3 fc) is composed of light-brown, fine- to medius-grained sand. Generally forms broad, smooth-surfaced plains which grade to the main valley of the Blackfoot River, and lim 1.5-6 m (5-20 ft) above the modern atream channel. Ground water commonly necurs at shallow depths.

Terrace Deposits--Gray, tan, brown, and pink; unconsulidated, moderately well sorted, well-bedded silt, sand, gravel, and cobbles in smooth-surfaced, dissected deposits flanking modern stream channels, and in abandoned channels 5-6 m (15-20 ft) above modern stream channels. These deposits are typically moderately to well-drained, and are inferred to have relatively low shrink-swell potential

SEDIMENTS DEPOSITED BY HELTWATERS OF PINEDALE GLACIATION (UPPER PLEISTOCENE) -- OLDER ICE

Outwash--Dark brown, reddish brown, and brown; consists of moderately well sorted silt, sand, and subangular to rounded gravel and cobbly gravel. Forms smooth, locally dissected plains and terraces which lie 6-30 m (20-100 fe) above the younger outwash deposits. Ground water occurs or moderate depths

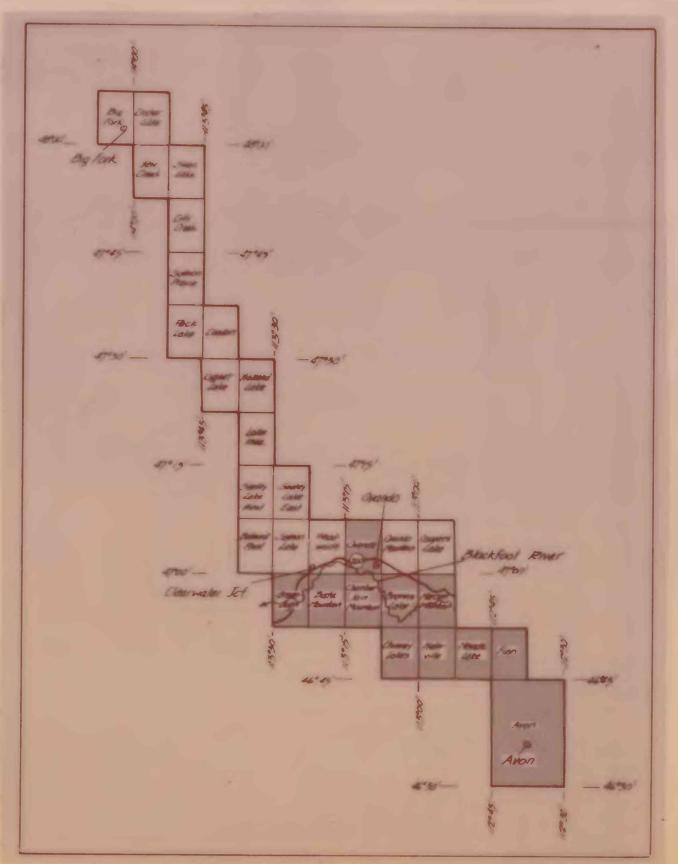

Outwash Fan Deposit -- Even-surfaced, gently sloping, coneshaped deposit of unconsolidated, moderately sorted silt, sand, gravel, and cobbles. Probably formed at some time after the Blackfoot River was diverted by lobes of ice Which lay in the Honture, North Fork of the Blackfoot, and Nevada Creek valleys

Deltaic Gravels -- Tan to brown; locally crossbedded, unconsolidated, well-sorted, medium- to coarse-grained sand, and gravel. Clasts range in shape from angular to round. Deposited in a small glacial lake formed where southward advancing Ice impinged upon the northern flank of the Garnet Range blocking the northward flowing ancestral Pearson Creek (see Chamberlain Hountain quadrangle)

TILL OF PINEBALE GLACIATION (UPPER PLEISTOCEME)

- Oty Till Deposited by Younger Ice--Characterized by a striking knob-and-kettle topography with many lakes and swamps. Consists of a heterogeneous assemblage of unsorted gravel, cobbles, and boulders in a light reddish-brown to tan silty to clayey matrix. Many large boulders are scattered across both the lateral and ground moralmes, and the terminal normina mear Eleinschmidt Lake; locally parts of the maraine surface slope as such as A5 percent. Clasts. range in shape from angular to well rounded, and are predominantly quartrities, argillites, and limentones of the Helt Supergroup. Soil drainage and persenbility is variable, but generally is pour
 - Till Deposited by Older Ice-Characterized by somewhat subdued knub-and-kettle topography. Constats of a heterogeneous assemblage of gravel, cobbins, and boulders in a reddish-brown, dense, granular, malcareous, claye) to milty, locally sendy matrix. Generally less than 13 percent of the rill is gravel size or larger. Sparse boulders are scattered across both the lateral and ground moralnes; surface slopes are commonly less than 25 percent. Clasta range in shape from angular to well rounded, and are predominantly quartities, argillites, and limestones of the Belt Supergroup. Soil drainage and permeability generally is poor
- DUTVASH OF BULL LAKE(?) ICE (PLEISTOCENE) -- Brown and reddish brown; unconsulidated, mildly calcareous, well-bedded and moderately well sorted silt, sand, gravel, and cobbles. Forms even-surfaced, gently sloping, highly dissected remnants which are about 12 o (40 ft) above the outwash of the older ice. Soil drainage is moderate to good
 - TYLL DEPOSITED BY BULL LAKE(?) ICE (FLEISTOCENE) -- A generally formless, gently andulating deposit of low relief characterized by sparse kettle depressions, and a few boulders scattered across the surface. Consists of an unconsolidated, unsorted assemblage of sand, gravel, cobbles, and boulders in a brown to reddish-brown, compact, clayer carrix. Locally large glacial boulders, 1-4 m (10-13 ft) across, are scattered through the till; they are especially common near Minemile Prairie (see Greenough quadrangle). Clay content is higher and this till consequently is more susceptible to mass movement than the younger tills. Where deeply dissected yields a discontinuous rubble weneer of cobbles and boulders

- FIREMONT ALLDVIDE (DUATERMARY AND TERTIARY) -- Reddish brown and tan; unconsolidated, anderstely well sorted, stratified silty sand and silt, sand, and gravel which mantle broad, smooth-surfaces benches that flank the mountains in the Relaville-Avon area. Deposits thin basinward, and typically are coarser-grained sear the mountains. Overlies truncated pre-Tertiary and Tertiary sedimentary and volcanic rocks, and is segmented by modern stream valleys and gullies, Locally the upper part of the deposit is weakly comented by calcium carbonate. Soundness and durability of the gravel is quite variable but typically is pour if the gravels contain high percentages of volcanic rock types. Those deposits rich . in volcanic rock types are nost common in basins which are adjacent to extensive outcrops of volcanic rocks
- MASIN DEPOSITS, UNDIVIDED (TERTIARY) -- Brown, grayish brown, and yellowish brown; semiconsolidated to consolidated clays, shales, siltstones, and sandstones with minor amounts of conglomerate. Also included are white, gray, brown, yellowish brown, and red beds of altered volcanic ash, and ash-rich shale and siltstone. Competence is fair to good in the brown siltstones and sandstones but poor in the light-colored shales, clays, and ash beds. "Popcorn" surface on the shales, clays, and ash hads indicate a high-swell potential. Soil drainage is fair to poor. In many localities this unit undeclies till, outwash, or alluvium and restricts and controls the downward and lateral migration of the local ground water
- VOLCANIC ROCKS, UNDIVIDED (TERTIARY) -- Small outcops of trachyte, andesite, lamprophyre, and extrusive volcanic breccia are in the western part of the area near Greenough (see Greenough quadrangle). Extensive basalt and andexite flows, volcanic breccias, and minor amounts of rhyolite, datite, diorite, gabbro, latite, and welded tuff are in the eastern part of the area near Helmville and Avon (see Melmylile and Avon quadrangles). The volcanic breccias are clay rich and very susceptible to mass movement
- QUARTZ MONZOWITE INTRUSIVE ROCKS (TERTIARY AND CRETACHOUS) --Consists of the Intrusive Carnet stock and other smaller ignsous bodies. Generally shows well-developed blocky jointing; weathers to spheroidal boulders. Gold minerals are in quartz veins that fill fractures in the quarte monsonite in a zone within about half a mile of the surrounding marble and limestone country rock
- ACTRIC AND INTERMEDIATE INTRUSIVE ROCKS (TERTIARY AND CRETACEONS) -- Includes small intrusive igneous bodies ranging in composition from quarts monnonite to ducite
- CRETACROUS AND JURASSIC BENEOUR, SUBIVIDED-Folded and faulted outcrops of (in descending order) the Cretaceous Blackleaf and Rootenat Formations and the Juraneic Swift, Rierdon, and Sawtooth Formations
- PERMIAN TO MISSISSIFFIAS BEDROCK, UNDIVIDED-Folded and faulted outcrops of the Phosphoria and Quadrant Formations, and the Madison Group. Locally some Limpstone and dolomite beds of the Jefferson Formation (Devonian) may be included with the Madison Group
- CAMBRIAN STRATA, UNDIVIDED-Folded, faulted and locally introded and metamorphoses outcroys of the (in descending order) Hassark and Silver Hill Formations and Flathead Quattrite. Near the Carnet stock the Ilmestones of the Hasnark(?) and Rilver Hills Formations have been metamorphosed to marble
- BELT SUPERGROUP ROCKS, UNDIVIDED (PRECAMBRIAN) -- Consists of various units of the Belt Supergroup, chiefly the Mount Shields (argillite and sandstone), Shepard (argillite and dolomite), and Snowslip (argillice and sandscone) Formations in the northern part of the area; and the quartiite and claystone of Black Mountain, Bonner Quartrice and the Mount Shields, Shepard, and Snowslip (calcareous audstone and quartelte) Formations in the southern part of the area

Index map showing quadrangles in the big Fork-Avon area. Those quadrangles in Open-Pile Reports 79-437 to 79-347 are abades.
